RED RUFFED LEMUR

Varecia rubra

1. What can it see, hear, or feel?
It smells scent marks, listens for barking alarms, and uses sharp eyes to judge branch to branch.

2. Where does it live — and why?
It lives only in one rainforest corner of Madagascar, where tall trees carry fruit all year.

3. How does it send messages?
It gives loud barking calls to warn of danger and roars with the group to claim its home.

4. What does it do when something changes?
When a predator is near, it calls out, moves quietly together, and hides in the thick trees.

5. How does it learn?
Babies follow their mother, watch which trees hold ripe fruit, and learn alarm calls early in life.

6. How does it have babies?
A mother builds a high nest and has two or three babies; other adults help guard them.

7. What are its limits?
It needs a large, healthy rainforest. With so little left, it is critically endangered.

8. What does this teach us?
An animal that depends on one small forest teaches us how fragile an environment can be.

WHY IS THIS ANIMAL HERE?

Red ruffed lemurs live in only one small corner of Madagascar.
Most of their rainforest has been cut down or changed by people.
What is left is broken into small, isolated patches.

When its habitat shrinks:

- fruit and food trees disappear
- groups become cut off from each other
- survival gets harder each year

This place is not their natural home, but it can help keep the species alive.
LIFE Park cares for one of the largest lemur populations in the United States, acting as a bridge while the wild recovers.

THINK ABOUT THIS

If you could only hear or smell instead of see, how different would your world be?

What a living thing can sense becomes its reality.
Environment shapes design.
