BENNETT'S WALLABY

Macropus rufogriseus

Think About This

If your back legs were your main way to move, how would you choose a safe place to rest?

What can it see, hear, or feel?

Each ear turns on its own, wide eyes see almost all around, and its feet feel ground vibrations.

Where does it live — and why?

It lives in eucalypt forest with open grassy spots — shade to rest and grass to graze.

How does it send messages?

It thumps a back foot to warn other wallabies, and a heavy, fast hop tells the group to scatter.

What does it do when something changes?

It rests in shade during the hottest part of the day and hops into thick brush when scared.

How does it learn?

A joey travels in its mother's pouch and watches what she eats before grazing on its own.

How does it have babies?

A tiny newborn crawls into the pouch and grows there, nursing for about nine months.

What are its limits?

It needs both open grass and dense cover, so clearing the forest leaves it exposed to dogs.

What does this teach us?

Its daily routine is timed around heat, not just hunger — environment shapes its whole day.

What a living thing can sense becomes its reality. Environment shapes design.
